

Introduction

md-publisher turns a folder of mdpub files into DOCX, PDF, Web, and EPUB output from one command. This guide walks through installing the CLI, building your first Publication, and where to go next.

See Setup to install the CLI, or jump straight to Advanced Topics if you already have it running.

Setup

Install md-publisher-cli globally with npm, then create a Publication: a directory of mdpub files, numbered so their filenames sort into the chapter order you want.

Run the generate command against that directory, naming the Build Targets you want. Output is written to a dist folder next to where you ran the command.

See Introduction for the big picture, or continue to Advanced Topics.

Advanced Topics

Cross-References

A link like this one pointing at Setup only resolves if a heading named Setup exists somewhere in the Publication. If it does not, the build refuses to produce any output at all until the Structure Violation is fixed.

Table of Contents

EPUB output needs exactly one chapter whose front matter marks it as the table-of-contents source, which is what the Introduction chapter does.

See Introduction to start over from the beginning.
